Related Art

This invention relates to compounds that bind to the human protein HDM2 and interfere with its interaction with other proteins, especially the tumor suppressor protein p53. HDM2 is the expression product of hdm2, an oncogene that is overexpressed in a variety of cancers, especially soft tissue sarcomas (Momand, J., et al., Nucl. Acids Res. 26:3453-3459 (1998)).

p53 is a transcription factor that plays a pivotal role in the regulation of the balance between cell proliferation and cell growth arrest/apoptosis. Under normal conditions, the half-life of p53 is very short, and consequently the level of p53 in cells is low. However, in response to cellular DNA damage, cellular stress, or other factors, levels of p53 increase. This increase in p53 levels in turn increases the transcription of a number of genes which induces the cell to either arrest growth or undergo apoptosis (i.e., controlled cell death). The function of p53 is to prevent the uncontrolled proliferation of cells and thus protect the organism from the development of cancer (for a review, see Levine, A.J., Cell 88:323-331 (1997)).

p53 is a latent and short-lived transcription factor which is induced by, and is an integration point for, a range of cellular stresses including DNA damage, UV damage, spindle damage, hypoxia, inflammatory cytokines, viral infection, activated oncogenes, and ribonucleotide depletion. Activation of p53 mediates a change in the balance of gene expression such that expression of many genes involved in proliferation is repressed while a range of genes involved in growth arrest (such as p21WAF1 and GADD45), repair (such as p53RE) and apoptosis (such as Bax, Killer/DR5 and PIGs) is activated. The biological outcome of p53 activation (whether permanent or transient growth arrest or apoptosis) is dependent on several factors including the type and strength of the inducing stress, and the type of cell or tissue.

p53 and MDM2 exist in a negative regulatory feedback loop in which p53 stimulates transcription of the mdm2 gene while MDM2 binds to p53 and targets it for degradation by the 26S proteasome. The key element in the p53 induction process is disruption of the p53-MDM2 complex which permits p53 to accumulate in the nucleus. This mechanism appears to be common to all of the pathways by which p53 becomes activated, although recent evidence has indicated that there is considerable variation in the molecular events by which this is actually achieved.

Inactivation of the p53 tumor suppressor is a frequent event in human neoplasia. The inactivation can occur by mutation of the p53 gene or through binding to viral or cellular oncogene proteins, such as the SV40 large T antigen and MDM2. While the mechanism through which wild-type p53 suppresses tumor cell growth is as yet poorly defined, it is clear that one key feature of the growth suppression is the property of p53 to act as a transcription factor (Farmer, G., et al., Nature 358:83-86 (1992); Funk, W. D. et al., Mol. Cell. Biol. 12: 2866- 2871 (1992); Kern, S. E., et al., Science 256:827-830 (1992)). Currently, considerable effort is being made to identify growth control genes that are regulated by p53 binding to sequence elements near or within these genes. A number of such genes have been identified. In cases such as the muscle creatine kinase gene (Weintraub, H., et al., Proc.

Natl. Acad. Sci. U.S.A., 88:4570-4571 (1991); Zambetti, G. P., et al., Genes Dev. 6:1143-1152 (1992)) and a GLN retroviral element (Zauberman, A., et al., EMBO J. 12:2799-2808 (1993)), the role these genes might play in the suppression of growth control is unclear. Yet there are other examples, namely mdm2 (Barak, Y., et al. EMBO J. 12:461-468 (1993); Wu, X., et al., Genes Dev. 7:1126-1132(1993)) GADD 45 (Kastan, M. B., et al., Cell 71:587-597(1992)) and WAF1 or CIP1 (El-Beiry, W. S., et al., Cell 75:817-825 (1993); Harper, J. W., et al., Cell 75:805-816 (1993)), where their involvement in the regulation of cell growth is better understood.

mdm2, a known oncogene, was originally found on mouse double minute chromosomes (Cahilly-Snyder., L., et al., Somatic Cell Mol. Genet. 13:235-244 (1987)). Its protein product was subsequently found to form a complex with p53, which was first observed in a rat fibroblast cell line (Clone 6) previously transfected with a temperature sensitive mouse p53 gene (Michalovitz, D., et al., Cell 62:671-680 (1990)). The rat cell line grew well at 37°C but exhibited a G1 arrest when shifted down to 32°C, which was entirely consistent with an observed temperature dependent switch in p53 conformation and activity. However, the p53-MDM2 complex was only observed in abundance at 32°C, at which temperature p53 was predominantly in a functional or "wild-type" form (Barak, Y. et al., EMBO J. 11:2115-2121 (1992) and Momand, J., et al., Cell 69:1237-1245 (1992)). By shifting the rat cell line down to 32°C and blocking de novo protein synthesis it was shown that only "wild-type" p53 induced expression of the mdm2 gene, thereby accounting for the differential abundance of the complex in terms of p53 transcriptional activity (Barak, Y., et al., EMBO J. 12:461-468 (1993)). The explanation was further developed by the identification of a DNA binding site for wild-type p53 within the first intron of the mdm2 gene (Wu, X., et al., Genes Dev. 7:1126-1132 (1993)). Reporter constructs employing this p53 DNA binding site revealed that they were inactivated when wild-type p53 was co-expressed with MDM2.

This inhibition of the transcriptional activity of p53 may be caused by MDM2 blocking the activation domain of p53 and/or the DNA binding site. Consequently, it was proposed that mdm2 expression is autoregulated, via the inhibitory effect of MDM2 protein on the transcriptional activity of wild-type p53. This p53-mdm2 autoregulatory feedback loop provided a novel insight as to how cell growth might be regulated by p53. Up to a third of human sarcomas are considered to overcome p53-regulated growth control by amplification of the hdm2 gene (the human homologue of mdm2) (Oliner, J.D., et al., Nature 358:80-83 (1992)). Hence, the interaction between p53 and HDM2 represents a key potential therapeutic target. One mechanism by which MDM2 can promote tumorogenesis is by its inhibitory action on p53. The tumor suppressor functions of p53 control a pivotal checkpoint in the control of cell cycling (reviewed in Levine, A.J., Cell 88:323-331 (1997)). p53 is a transcription factor for a number of proteins that cause cell cycle arrest or cell death by apoptosis. The level and transcriptional activity of p53 are increased by damage to cellular DNA. The MDM2 protein inhibits p53 function by binding to an amphipathic N-terminal helix of p53, abrogating the interaction of p53 with other proteins and its transactivation activity. The interaction with MDM2 also targets p53 for ubiquitin dependent protein degradation. MDM2 exhibits p53 independent effects on cell cycling as well, possibly by direct interaction with some of the downstream effectors such as pRB and EF2 (Reviewed in Zhang, R. and Wang, H., Cur. Pharm. Des. 6:393-416 (2000)).

Blocking HDM2 from binding p53 would be therapeutically useful in restoring cell cycle control to cells that overexpress HDM2 as a front line cancer treatment. More generally, inhibition of HDM2 may increase the effectiveness of chemotherapy and radiation in p53 normal cancers by enhancing apoptosis and growth arrest signaling pathways.

A need continues to exist for potent, small molecules that inhibit the interactions between HDM2 and p53.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

A novel class of small molecules that bind to HDM2 and/or MDM2 has now been discovered. By interfering with HDM2-p53 or MDM2-p53

interactions, these compounds increase the intracellular concentration of p53. These small molecules, therefore, have therapeutic utility in sensitizing tumor cells for chemotherapy. In tumor types particularly sensitive to an increase in functional p53, compounds of this type will be sufficient to induce apoptosis. Compounds of the present invention are also useful in treating tumor types in which HDM2 or MDM2 is overexpressed.

The invention disclosed herein is also meant to encompass the *in vivo* metabolic products of the disclosed compounds. Such products may result for example from the oxidation, reduction, hydrolysis, amidation, esterification and the like of the administered compound, primarily due to enzymatic processes. Accordingly, the invention includes compounds produced by a process comprising contacting a compound of this invention with a mammal for a period of time sufficient to yield a metabolic product thereof. Such products typically are identified by preparing a radiolabeled compound of the invention, administering it parenterally in a detectable dose to an animal such as rat, mouse, guinea pig, monkey, or to man, allowing sufficient time for metabolism to occur and isolating its conversion products from the urine, blood or other biological samples.

Some of the compounds disclosed herein may contain one or more asymmetric centers and thus give rise to enantiomers, diastereomers, and other stereoisomeric forms. The present invention is also meant to encompass all such possible forms as well as their racemic and resolved forms and mixtures thereof. When the compounds described herein contain olefinic double bonds or other centers of geometric asymmetry, and unless specified otherwise, it is intended to include both E and Z geometric isomers. All tautomers are intended to be encompassed by the present invention as well.

As used herein, the term "stereoisomers" is a general term for all isomers of individual molecules that differ only in the orientation of their

atoms in space. It includes enantiomers and isomers of compounds with more than one chiral center that are not mirror images of one another (diastereomers).

The term "chiral center" refers to a carbon atom to which four different groups are attached, or a sulfur atom to which three different groups are attached, where the sulfur atom and its attached groups form a sulfoxide, sulfinic ester, sulfonium salt or sulfite.

The term "enantiomer" or "enantiomeric" refers to a molecule that is nonsuperimposable on its mirror image and hence optically active wherein the enantiomer rotates the plane of polarized light in one direction and its mirror image rotates the plane of polarized light in the opposite direction.

The term "racemic" refers to a mixture of equal parts of enantiomers and which is optically inactive.

The term "resolution" refers to the separation or concentration or depletion of one of the two enantiomeric forms of a molecule. The phrase "enantiomeric excess" refers to a mixture wherein one enantiomer is present is a greater concentration than its mirror image molecule.

The compounds of Formula *I* may also be solvated, especially hydrated. Hydration may occur during manufacturing of the compounds or compositions comprising the compounds, or the hydration may occur over time due to the hygroscopic nature of the compounds.

Certain compounds within the scope of Formula *I* are derivatives referred to as "prodrugs." The expression "prodrug" denotes a derivative of a known direct acting drug, which derivative has enhanced delivery characteristics and therapeutic value as compared to the drug, and is transformed into the active drug by an enzymatic or chemical process. Prodrugs are derivatives of the compounds of the invention which have metabolically cleavable groups and become by solvolysis or under physiological conditions the compounds of the invention which are pharmaceutically active *in vivo*. For example, ester derivatives of compounds of this invention are often active *in vivo*, but not *in vitro*. Other derivatives of

the compounds of this invention have activity in both their acid and acid derivative forms, but the acid derivative form often offers advantages of solubility, tissue compatibility, or delayed release in the mammalian organism (see, Bundgard, H., Design of Prodrugs, pp. 7-9, 21-24, Elsevier, Amsterdam 1985). Prodrugs include acid derivatives well known to practitioners of the art, such as, for example, esters prepared by reaction of the parent acid with a suitable alcohol, or amides prepared by reaction of the parent acid compound with an amine. Simple aliphatic or aromatic esters derived from acidic groups pendent on the compounds of this invention are preferred prodrugs. In some cases it is desirable to prepare double ester type prodrugs such as (acyloxy) alkyl esters or ((alkoxycarbonyl)oxy)alkyl esters. Useful prodrugs are those where R^b is alkyl, alkenyl, alkynyl, or arylalkyl.

When any variable occurs more than one time in any constituent or in Formula *I*, its definition on each occurrence is independent of its definition at every other occurrence. Also, combinations of substituents and/or variables are permissible only if such combinations result in stable compounds.

Compositions and Methods of Use

Compositions of the present invention include pharmaceutical compositions comprising a compound of Formula *I*, wherein R¹-R¹¹ and X are defined above, and one or more pharmaceutically acceptable excipients. Preferred compositions of the present invention are pharmaceutical compositions comprising a compound selected from a preferred group of compounds of Formula *I* as defined above, and one or more pharmaceutically acceptable excipients.

The pharmaceutical compositions of the invention can be administered to any animal that can experience the beneficial effects of the compounds of the invention. Foremost among such animals are humans, although the invention is not intended to be so limited.

The pharmaceutical compositions of the present invention can be administered by any means that achieve their intended purpose. For example, by administration can be subcutaneous, intravenous, intramuscular, intraperitoneal, buccal, ocular routes, rectally, parenterally, intrasystemically, intravaginally, topically (as by powders, ointments, drops or transdermal patch), or as an oral or nasal spray. Alternatively, or concurrently, administration can be by the oral route. The dosage administered will be dependent upon the age, health, and weight of the recipient, kind of concurrent treatment, if any, frequency of treatment, and the nature of the effect desired.

In addition to the pharmacologically active compounds, the new pharmaceutical preparations can contain suitable pharmaceutically acceptable carriers comprising excipients and auxiliaries that facilitate processing of the active compounds into preparations that can be used pharmaceutically.

The pharmaceutical preparations of the present invention are manufactured in a manner that is, itself, known, for example, by means of conventional mixing, granulating, dragée-making, dissolving, or lyophilizing processes. Thus, pharmaceutical preparations for oral use can be obtained by combining the active compounds with solid excipients, optionally grinding the resulting mixture and processing the mixture of granules, after adding suitable auxiliaries, if desired or necessary, to obtain tablets or dragée cores.

Suitable excipients are, in particular, fillers such as saccharides, for example, lactose or sucrose, mannitol or sorbitol, cellulose preparations and/or calcium phosphates, for example, tricalcium phosphate or calcium hydrogen phosphate, as well as binders, such as, starch paste, using, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, tragacanth, methyl cellulose, hydroxypropyl methylcellulose, sodium carboxymethylcellulose, and/or polyvinyl pyrrolidone. If desired, disintegrating agents can be added, such as, the above-mentioned starches and also carboxymethyl-starch, crosslinked polyvinyl pyrrolidone, agar, or alginic acid or a salt thereof, such as, Auxiliaries are, above all, flow-regulating agents and sodium alginate. lubricants, for example, silica, talc, stearic acid or salts thereof, such as, magnesium stearate or calcium stearate, and/or polyethylene glycol. Dragée cores are provided with suitable coatings that, if desired, are resistant to gastric juices. For this purpose, concentrated saccharide solutions can be used, which can contain gum arabic, talc, polyvinyl pyrrolidone, polyethylene glycol, and/or titanium dioxide, lacquer solutions and suitable organic solvents or solvent mixtures. In order to produce coatings resistant to gastric juices, solutions of suitable cellulose preparations, such as, acetylcellulose phthalate or hydroxypropylmethyl-cellulose phthalate, are used. Dye stuffs or pigments

can be added to the tablets or dragée coatings, for example, for identification or in order to characterize combinations of active compound doses.

Other pharmaceutical preparations which can be used orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer, such as, glycerol or sorbitol. The push-fit capsules can contain the active compounds in the form of granules that may be mixed with fillers such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate and, optionally, stabilizers. In soft capsules, the active compounds are preferably dissolved or suspended in suitable liquids, such as, fatty oils or liquid paraffin. In addition, stabilizers may be added.

Suitable formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form, for example, water-soluble salts, alkaline solutions and cyclodextrin inclusion complexes. Especially preferred alkaline salts are ammonium salts prepared, for example, with Tris, choline hydroxide, Bis-Tris propane, *N*-methylglucamine, or arginine. One or more modified or unmodified cyclodextrins can be employed to stabilize and increase the water solubility of compounds of the present invention. Useful cyclodextrins for this purpose are disclosed in U.S. Patent Nos. 4,727,064, 4,764,604, and 5,024,998.

In addition, suspensions of the active compounds as appropriate oily injection suspensions can be administered. Suitable lipophilic solvents or vehicles include fatty oils, for example, sesame oil, or synthetic fatty acid esters, for example, ethyl oleate or triglycerides or polyethylene glycol-400 (the compounds are soluble in PEG-400). Aqueous injection suspensions can contain substances that increase the viscosity of the suspension, for example, sodium carboxymethyl cellulose, sorbitol, and/or dextran. Optionally, the suspension may also contain stabilizers.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents,

solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, dimethyl formamide, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor, and sesame oils), glycerol, tetrahydrofurfuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof.

Suspensions, in addition to the active compounds, may contain suspending agents as, for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar, and tragacanth, and mixtures thereof.

Topical administration includes administration to the skin or mucosa, including surfaces of the lung and eye. Compositions for topical administration, including those for inhalation, may be prepared as a dry powder which may be pressurized or non-pressurized. In nonpressurized powder compositions, the active ingredients in finely divided form may be used in admixture with a larger-sized pharmaceutically acceptable inert carrier comprising particles having a size, for example, of up to 100 micrometers in diameter. Suitable inert carriers include sugars such as lactose. Desirably, at least 95% by weight of the particles of the active ingredient have an effective particle size in the range of 0.01 to 10 micrometers.

Alternatively, the composition may be pressurized and contain a compressed gas, such as nitrogen or a liquefied gas propellant. The liquefied propellant medium and indeed the total composition are preferably such that the active ingredients do not dissolve therein to any substantial extent. The pressurized composition may also contain a surface-active agent. The surface-active agent may be a liquid or solid non-ionic surface-active agent or may be a solid anionic surface-active agent. It is preferred to use the solid anionic surface-active agent in the form of a sodium salt.

A further form of topical administration is to the eye. The compounds and compositions of the present invention are delivered in a pharmaceutically acceptable ophthalmic vehicle, such that the compounds are maintained in contact with the ocular surface for a sufficient time period to allow the compounds to penetrate the corneal and internal regions of the eye, as for example the anterior chamber, posterior chamber, vitreous body, aqueous humor, vitreous humor, cornea, iris/ciliary, lens, choroid/retina and sclera. The pharmaceutically acceptable ophthalmic vehicle may, for example, be an ointment, vegetable oil or an encapsulating material.

Compositions for rectal or vaginal administration are preferably suppositories which can be prepared by mixing the compounds of the present invention with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol or a suppository wax which are solid at room temperature but liquid at body temperature and therefore melt in the rectum or vaginal cavity and release the drugs.

The compositions of the present invention can also be administered in the form of liposomes. As is known in the art, liposomes are generally derived from phospholipids or other lipid substances. Liposomes are formed by monoor multi-lamellar hydrated liquid crystals that are dispersed in an aqueous medium. Any non-toxic, physiologically acceptable and metabolizable lipid capable of forming liposomes can be used. The present compositions in liposome form can contain, in addition to the compounds of the present invention, stabilizers, preservatives, excipients, and the like. The preferred lipids are the phospholipids and the phosphatidyl cholines (lecithins), both natural and synthetic. Methods to form liposomes are known in the art (see, for example, Prescott, Ed., *Meth. Cell Biol. 14*:33 (1976)).

The following examples illustrate, but do not limit, the compounds, methods and compositions of the present invention. Other suitable modifications and adaptations of the variety of conditions and parameters normally encountered in clinical therapy and which are obvious to those skilled in the art are within the spirit and scope of the invention.

EXAMPLES

The compounds in the examples below were synthesized by the following general procedures.

General procedure for the conventional synthesis of diazepine compounds

A solution of the aldehyde (0.20 mmol) and amine (0.20 mmol) in methanol (2.0 mL) were stirred at ambient temperature for 30 min. To this solution was added a solution of cyclohexene-1-isonitrile (0.21 mmol) in hexanes, followed by the aryl or heteroaryl amino acid (0.20 mmol). The solution was then stirred for 3 days at ambient temperature. Acetyl chloride (0.2 mL) was added slowly. The solution was then shaken for an additional 3 h and concentrated in vacuo. The residue was purified using pre-packed silica cartridges (methylene chloride to 10 % ethyl acetate in methylene chloride). The residue was purified using pre-packed silica cartridges (8 % ethyl acetate in methylene chloride to 10 % methanol in methylene chloride) to give the title compounds.

General procedure for the alkylation of diazepines at position 1

Alkylating agent (1.5 equiv) was added to oven dried 2-dram vial equipped with a stir bar under nitrogen. The diazepine to be alkylated (1.0 equiv) was added, and the resulting mixture was dissolved in a solvent, such as DMF. Potassium carbonate (2.0 equiv.) was added, followed by addition of tetrebutylammonium iodide (catalytic). The reaction mixture was tightly capped and heated to 80 °C overnight. The reaction was filtered, concentrated down, and loaded onto a 1000 μm TLC plate. After elution twice with 10% EtOAc/hexanes, the lower band was isolated to give the 1-alkylated compounds.

General procedure for the synthesis of amidines

A solution of 1,4-benzodiazepine-2,5-dione (0.181 mmol), 4-(*N*,*N*-dimethylamino)pyridine (122 mg, 1.0 mmol), and phosphorus oxychloride (350 μL, 1.4 mmol) in dichloroethane (4 mL) was stirred at 135 °C in a sealed tube for 2 h. After the solution was cooled to room temperature, the excess of phosphorus oxychloride was removed under vacuum. Then, the residue was dissolved in dry CH₂Cl₂ (6 mL), and amine (2-10 equiv) was added dropwise with stirring at 0 °C under argon. After 10 min, the reaction mixture was allowed to warm to room temperature. Then, the solvent was evaporated and the residue was chromatographed on silica (EtOAc/hexanes, 1:1) to give the title compounds as a colorless solid.

General procedure for the alternative diazepine synthesis #1

A solution of isatoic anhydride (1 mmol) and amino acid ester (1.3 mmol) in pyridine (3 mL) was stirred at 125 °C in a sealed tube for 1.5 h. After cooling to room temperature, the solvent was removed under vacuum. Chromatography on silica (EtOAc/hexanes, 1:1) afforded the appropriately substituted *N*-(2-aminobenzoyl)-2-(aryl)glycine methyl ester, which was dissolved in THF (10 mL). Then, potassium *tert*-butoxide (1M in THF, 1.1 mL) was slowly added, at -78°C under argon atmosphere. The reaction mixture was allowed to warm up to room temperature. After 14 h., the reaction was quenched with acetic acid (150 μL), then the solvent was evaporated to dryness and the residue was diluted with ethyl acetate, washed with water, dried (Na₂SO₄), and concentrated to dryness under reduced pressure. Chromatography on silica (AcOEt/Hexane, 1:1) afforded the diazepine compound as colorless prisms. Alternatively, isatoic anhydride (10) was treated with a base such as NaH, in a solvent such as DMF at 0°C to room

temperature, followed by addition of a substituted halogen derivative to give (13). This was treated with an amino ester (1.5 equiv) at $80-120^{\circ}$ C, followed by addition of t-BuOK at -20° C to room temperature to give the title compound. General procedure for the alternative diazepine synthesis #2

A solution of α-haloester (10 mmol), an optionally-substituted amine (10 mmol), K₂CO₃ (20 mmol) and TBAI (1.35 mmol) were stirred in acetonitrile at 45°C for 12 hours. The crude mixture was extracted from water with ethyl acetate, followed by chromatography on silica (EtOAc:Hexane 5:95). The product (3.0 mmol) was treated with DIEA (11.5 mmol) in DCM (30 mL), followed by addition of an optionally-substituted α,β -unsaturated amine (3.25) mmol) at 0°C. The crude reaction was extracted from water with EtOAc, followed by chromatography on silica (Hexane: EtOAc 8:1) to give the corresponding product. This product (1.0 mmol) was saponified with NaOH (15.0 mmol) in THF and methanol at room temperature, followed by extraction from 1N HCl with EtOAc. The acid (0.88 mmol) was then treated with ammonium chloride (1.76 mmol), PyBrOP (1.32 mmol), HOBt (1.32 mmol) and DIEA (3.52 mmol) in DMF (3 mL) at room temperature and stirred for 2 hours. The crude mixture was extracted from water with EtOAc and purified by chromatography on silica (AcOEt: Hexane 1:3). The resulting amide (3.3 mmol) was stirred with silver triflate (6.6 mmol) in acetonitrile (120 mL) at room temperature. Benzeneselenyl bromide (6.53 mmol) was added in DMF (5.2 mL) and stirred for 2 hours. The crude residue was extracted from water with EtOAc and purified by chromatography (AcOEt:hexane 1:3). The corresponding product (0.49 mmol) was treated with hydrogen peroxide (500 µL, 30% in water) in THF at room temperature and stirred for 20 minutes. The crude mixture was extracted from 1N sodium hydrogencarbonate with EtOAc, followed by chromatography on silca (AcOEt:hexanes:DCM 1:2:2) to give the title compound.

General procedure for the dialkylation of diazepines

A base, such as potassium carbonate (0.88 mmol) was added, at 20°C to a stirred solution of diazepine (11) (0.82 mmol) in anhydrous DMF (4 mL). After 10 min., optionally-substituted alkyl halide (0.96 mmol) was added and stirring was continued for 1-12 h. at $25\text{-}70^{\circ}\text{C}$. Then, the reaction was diluted with ice-cold water (30 mL), and the residue filtered, washed with water, then dried in vacuo. Next, a base, such as $K_2\text{CO}_3$ (1.1 equiv) was added at 0°C to this product in anhydrous solvent, such as DMF (2 mL). After 10 min., optionally-substituted alkyl halide (0.32 mmol) was added and stirring was continued for 5-24 h. at $25\text{-}80^{\circ}\text{C}$. Then, the reaction was quenched with acetic acid (50 µL). The crude material was purified by column chromatography on silica (EtOAc/hexane, 1.1). Recrystallization from ethanol/ether yielded the compound 12 as colorless crystals.

EXAMPLE 115

Fluorescent peptide assay

The inhibition of MDM2 binding to p53 was measured using a p53 peptide analogue binding to MDM2 residues 17-125. The published crystal structure of this complex (Kussie *et al.*, *Science 274*:948-953 (1996)) validates this fragment as containing the p53 binding site, and we have solved the x-ray structure of the p53 peptide analogue MPRFMDYWEGLN, described to be a peptide inhibitor of the MDM2 p53 interaction (Bottger *et al.*, *J. Mol. Biol.*

269:744-756 (1997)). The assay uses N terminal fluorescein RFMDYWEGL peptide (Fl 9mer).

The mdm2 17-125 was produced as a glutathione S transferase fusion as follows: cDNA encoding residues 17-125 were cloned into pGEX4t-3 (Pharmacia) as follows. PCR was performed using ATCC item number 384988 containing partial human mdm2 sequence as template and the following primers: Forward: 5'-CTC TCT CGG ATC CCA GAT TCC AGC TTC GGA ACA AGA G; Reverse: 5'-TAT ATA TCT CGA GTC AGT TCT CAC TCA CAG ATG TAC CTG AG. The PCR product was then digested with BamHI and XhoI (sequence recognition sites underlined in primers), gel purified, and ligated into pGEX4t-3 which had also been digested with BamHI and XhoI. Plasmids were transfected into E. coli X90 strain, grown to an OD of 1.0 in TB 0.2% glucose 100 µg/mL ampicillin and induced with 1 mM IPTG. Cells were harvested 5 hours post induction, centrifuged, and resuspended in PBS 10 mL/g cell paste. Cells were lysed in an Avestin microfluidizer, centrifuged, and the supernatant bound to a glutathione sepharose 4B resin (Pharmacia). The resin was washed with PBS and the MDM2 17-125 cleaved from the GST by the addition of 2 µg/mL thrombin (Enzyme Research Labs). The cleaved MDM2 was further purified on Sepharose SP Fast Flow resin (Pharmacia), eluting with 20 mM HEPES pH 7.5 150 mM NaCl. Glutathione was added to 5 mM, and the protein stored at -70°C.

Test compound was incubated for 15 minutes with 30 nM fluorescein peptide Fl 9mer and 120 nM MDM2 17-125 in 50 mM HEPES pH 7.5, 150 mM NaCl, 3 mM octyl glucoside. The polarization of the fluorescein label was thereafter measured by excitation at 485 nm and emission at 530 nm. Polarization was expressed as a percent of a no compound control, using buffer with Fl 9mer but without MDM2 as background.

Compounds of the present invention inhibited the binding of p53 to MDM2. The potency of the compounds was measured as IC_{50} , which is a measure of the concentration of the test compound required to inhibit 50% binding

between MDM2 and p53. The IC $_{50}$ values for compounds of the present invention ranged from 0.05 μ M to >100 μ M. See examples below.
